Oxygen is essential for seed germination.

Read Book Seed Physiology Germination

The initial phase of seed germination may involve anaerobic respiration but immediately it shifts to aerobic state. In a seed where testa is retained the oxygen consumption is much higher than in the seeds where testa has been removed.

And Reserve Accumulation
Species are able to germinate a few days after ovule fertilization. In this case, germination refers to protrusion of the primary root, not the formation of a normal seedling because histodifferentiation has not been completed and reserve accumulation is still incipient at this phase.
